# Asynchronous Programming in JS - 2

Relevel by Unacademy

### **Promises**

 An object that represents the completion (or failure) of an asynchronous operation and also its resulting value is known as a promise.

```
const newPromise = new Promise((resolve, reject) => {
  console.log("Promise created");
  setTimeout(() => {
       reject ("Some Error");
  console.log("Exit from promise")
console.log("First txt in sync");
newPromise
   .then((result) => {
      console.log("success:", result);
      console.log("Faliure:", error);
   .finally(() => {
      console.log("Promise completed");
console.log("Last txt sync");
```

### **Promise Hell**

Promise hell is a self created problem due to lack of understanding of Promises, unlike callback hell. In Promise hell as well we have to wait for other promises to return and it will fill the stack.

```
fetchStory()
   .then((story) => {
       return findText(story);
   .then((txt) \Rightarrow {
       return print(txt);
  });
fetchStory()
   .then((story) => findText(story))
   .then((txt) => print(txt));
fetchStory()
   .then(findText)
   .then(print);
```

### **Promise.all**

- It is a method that takes an array of promises and return new promise only when all promises will be fulfilled.
- It works asynchronous. So, if there is independent promises. We can add it into Promise.all() and it will try to resolve it parally.

```
connectDB()
  .then((database) => {
    return findMenu(database)
        .then((menu) => {
        return getUser(database)
        .then((user) => {
            return suggestItems(menu, user);
        });
    });
}
```

```
const databasePromise = connectDB();
const menuPromise = menuPromise
   .then(findMenu);
const userPromise = databasePromise
   .then(getUser);
Promise.all([
   menuPromise,
   userPromise
])
   .then(([menu, user]) => suggestItems(menu, user));
```

## **Async/Await**

- Async/ Await is used to handle promises in synchronous code fashion with less code effort.
- Async: We put this keyword before any function then, it will return a promise.
- Await: This keyword is used before a promise inside the Async block to block the code until promise resolves or reject.
- So, these keyword helps us to get write a synchronous fashion code with cleaner syntax.

```
st first = () => new Promise(resolve => {
  setTimeout(() => resolve('first()'), 1000);
 onst second = () => new Promise(resolve => {
  setTimeout(() => resolve('second()'), 1000);
 onst third = () => new Promise(resolve => {
  setTimeout(() => resolve('third()'), 1000);
 omise.all([first(), second(), third(), { someKey: someValue }])
  .then((data) => {
      console.log("success:", data);
  .catch((err) => {
      console.log("error:", err);
 nst process = async () => {
  const first = await a();
  const second = await b();
  const third = await c();
  return [first, second, third];
process
  .then((data) => {
      console.log("success:", data);
      console.log("error:", err);
```

### **Iterators and Generators**

#### Iterators:

These are the object with a sequence and able to return values when terminates.

These follows Iterators protocol by having a next() method that returns two properties:

- 1. Value: The next value in the sequence.
- Done: Indicates whether that was the last value in the sequence or not by returning true and false. True when ends, false in the middle of iteration.

#### **Generators:**

So, to create a iterator we need careful programing. Generator makes it very easier. It helps us to define the algorithm of iteration in a single function where execution is not continuous,

It is a special type of iterator, and written with syntax function\*.

```
rangeIterator(begin = 0, end = Infinity, step = 1)
  let nextIndex = begin;
    next: function() (
         let result;
        if (nextIndex < end) {
             result = { value: nextIndex, done: false }
             nextIndex += step;
             iterationCount++;
             return result;
         return { value: iterationCount, done: true }
 nst it = rangeIterator(1, 20, 3);
nile (!response.done) {
esponse = it.next();
onsole.log("Iterated over sequence of size: ", response.value); // Iterated over
```

```
function* rangeIterator(begin = 0, end = 100, step = 1) {
  let iterationCount = 0;
  for (let i = begin; i < end; i += step) {
    iterationCount++;
    yield i;
  }
  return iterationCount;
}</pre>
```

### **Inversion of Control**

An abstract programming principle based on the flow of control that should be managed completely by some specific implementation of the framework, which is external to your code.

```
unction filter(array, filterFunction)
 let newArray = []
 for (let index = 0; index < array.length; index++) {</pre>
   const element = array[index]
   if (filterFunction(element)) {
     newArray[newArray.length] = element
 return newArray
console.log(filter(
el => el !== null && el !== undefined,
console.log(filter(array, el => el !== undefined))
console.log(filter(array, el => el !== null))
console.log(filter(array,
el => el !== undefined && el !== null && el !== 0,
console.log(filter(array,
el => el !== undefined && el !== null && el !== '',
```

### **Practice/HW**

- 1. Implement a map using the Inversion of Control principle that will perform operations on an array such as:
  - a. Squaring the elements
  - b. Dividing them by 5.
  - c. The root of the element
  - d. etc
- 2. Implement a generator that will return power all the powers of 3.
- 3. Program to explain difference between Promise.all() and Promise.race().

## Thank you
